Informe de actividades Dr. Marcos Hernández Rodríguez

1. Título proyecto:

Uso de métodos computacionales para estudiar agregados supramoleculares para reconocimiento de enantiómeros y catálisis

2. Resumen

Los recursos de supercómputo se usaron en entender procesos catalíticos y reconocimiento de enantiómeros. En los procesos catalíticos se llevaron a cabo dos proyectos: (1) entender el mecanismo como los silanodioles activan electrófilos y (2) modelado de estados de transición de catalizadores bifuncionales en la reacción de 2,4-pentanodiona con β -nitroestireno. En reconocimiento de enantiómeros se modelaron escuaramidas quirales con sustituyentes ariletilo y su aducto con *R* y *S* mandelato.

3. Breve descripción de avances

En la tesis de Hugo García Hernández se estudiaron silanodioles como catalizadores de enlace de hidrógeno (EH) en la reacción de Friedel-Crafts entre el indol y el β -nitroestireno. Experimentalmente se encontró que únicamente a concentraciones muy elevadas procedía la reacción. Esto nos sugirió que existía un agregado responsable de la catálisis y no la unidad monomérica. Por cálculos se encontró que la estructura dimérica es mas estable por 12.6 kcal/mol sobre el monómero y además ese dímero forma aductos mas estables con el electrófilo (De Δ E =-10 kcal/mol para el dímero y Δ E =-8.6 kcal/mol para el monómero).

Se continúo con el análisis de los agregados supramoleculares escuaramida quiral con *R* y *S*-mandelato. Las estabilidades relativas de los agregados diastereoméricos concuerdan con los resultados experimentales por lo que ayudan a fundamentar el proceso de enantiodiscriminación que llevan a cabo los receptores. En los casos de sustituyentes arilo pequeños y electrodonadores forman interacciones CH····π entre el grupo arilo de la escuaramida y el fenilo del mandelato los cuales se encuentran "isolado" en el aducto (Figura 1a y 1b) lo cual los hace mas estables que el aducto diastereomérico (Figura 1c). Este mismo razonamiento sirve para explicar otros sustituyentes los cuales no generan interacciones atractivas sino repulsivas como los grupos: 3,5-bistrifluorometilfenil, *ter*-butilo o naftilo donde la interacción isolado es repulsiva por su cercanía y se reconoce al enantiómero opuesto.

Figura 1. Reconocimiento de mandelatos quirales por la escuaramida C_2 con 1-feniletilo.

Se realizó modelado del estado de transición para la formación del enlace carbonocarbono para la reacción entre el β -nitroestireno y la acetilacetona promovida por catalizadores bifuncionales tiourea/amina terciaria. Se comparó el desempeño de pares de catalizadores diastereoméricos que contienen 1-feniletilo o 2,2,2-trifluoro-1feniletilo. En todos los casos se modeló la ruta para el enantiómero mayoritario y el minoritario. Se comparó con datos experimentales de velocidad de reacción experimental con energía de activación teórica Ea (diferencia de energía entre el TS y el intermediario previo para el enantiómero mayoritario) y enantioselectividad experimental con la enantioselectividad teórica como la diferencia de energías de activación entre los enantiómeros (Δ Ea). Los resultados explican las tendencias observadas entre pares de catalizadores diastereoméricos y mas importan te nos dio indicios de las interacciones atractivas responsables en la selectividad en cada caso.

4. Cálculos realizados

Para los cálculos teóricos de reconocimiento de enantiómeros y catálisis por silanodioles se empleó funcionales de la densidad (M06-2X/6-31+G(d,p) con optimización de geometría y cálculo de frecuencias. En el modelado de los estados de transición con catalizadores bifuncionales se optimizaron en M06-2X/6-31+G(d,p) y cada punto estacionario fue caracterizado como un mínimo o estado de transición por sus frecuencias armónicas. Se llevaron a cabo cálculos de coordenada de reacción en todos los casos para verificar la conectividad entre el estado de transición y los dos mínimos asociados al complejo reactivo y producto. Adicionalmente se hicieron cálculos de punto sencillo en SMD-(tolueno)-M06-2X/6-311++G(d,p) para tener un valor mas exacto en energía.

Supporting Information

ABSTRACT: Thioureas are an important scaffold in organocatalysis because of their ability to form hydrogen bonds that activate substrates and fix them in a defined position, which allows a given reaction to occur. Structures that enhance the acidity of the thiourea are usually used to increase the hydrogen-bonding properties, such as 3,5-bis(trifluoromethyl)phenyl and boronate ureas. Herein, we report the synthesis of bifunctional thioureas with a chiral moiety that include either a trifluoromethyl or methyl group. Their catalytic performance in representative Michael addition reactions was used in an effort to compare the electronic effects of the fluorination at the methyl group. The observed differences concerning yields and ee values cannot be attributed solely to the different steric environments; theoretical results indicate distinct interactions within the corresponding transition states.

The calculated transition states show that the fluorinated catalysts have stronger N–H···O and C–H···F hydrogen bonds, while the nonfluorinated systems have C–H··· π contacts. These results have shown that a variety of hydrogen-bonding interactions are important in determining the yield and selectivity of thiourea organocatalysis. These details can be further exploited in catalyst design.

■ INTRODUCTION

Hydrogen-bonding catalysis and a chiral counterion strategy have risen recently as a reliable synthetic methodology.¹ Takemoto² introduced chiral bifunctional catalysts³ to activate an electrophile through hydrogen bonds (HB). These systems also contain a tertiary amine that deprotonates a nucleophile which is subsequently added. The Takemoto catalyst (Figure 1a) features a

Figure 1. Moieties used to enhance hydrogen bond donor properties or to modulate steric effects in H-bond catalysis and counterion strategies.

3,5-bis(trifluoromethyl)phenyl group⁴ that enhances the acidity of the thiourea and thereby increases its hydrogen-bonding properties. Boronate ureas have a similarly enhanced HB donor capacity of the HNC(O) moiety, in this case by means of an internal Lewis acid.^{5,6} Stereocontrol of the addition products⁷ can be achieved by addition of chiral substituents to the thiourea moiety (Figure 1b); however, this is done at the expense of the HB activation ability. Nonetheless, if a chiral group with electronwithdrawing properties is bound to the thiourea (Figure 1c), a good compromise between the modulation of the steric demands and activation by the catalyst can be accomplished. On this subject, Ellman,⁸ Jacobsen, and others⁹ have used N-sulfinyl ureas that are able to catalyze a variety of reactions. Herein we report the synthesis and application of bifunctional thioureas with a chiral group that incorporates a trifluoromethyl group in its structure.¹⁰ Thioureas featuring trifluoromethyl groups have shown exceptional properties in the recognition of chiral carboxylates with binding constants that are 10 times higher than those for the analogous nonfluorinated compounds.¹¹ The chiral moiety with $-CF_3$ confers to the thioureas reported in this work (1) good HB properties¹² without the deactivation of the catalyst by intramolecular interactions¹³ and (2) the possibility of modulating the steric environment. In addition, the catalysts put forward in this are easily synthesized and allow the incorporation of a variety of functional groups in their structure. This study also considers the corresponding nonfluorinated catalysts¹ to provide insights into the effect of the NH acidity on the yield and enantiomeric excess of the reactions considered in this investigation.

The synthesis of the chiral scaffold with trifluoromethyl groups was performed by the nucleophilic addition of the Ruppert– Prakash reagent to (*S*)-*N*-tert-butylsulfinylimines **1a**–**d**, affording compounds **2a**–**d** with excellent diastereoselectivity.¹⁵ After removal of the chiral auxiliary, amines **3a**–**d** were transformed to isothiocyanates **4a**–**d** and added to both enantiomers of *trans*-*N*,*N*-dimethyl-1,2-diaminocyclohexane¹⁶ to produce the diastereomeric catalysts (*R*,*S*,*S*)-**5a**–**d** and (*R*,*R*,*R*)-**6a**–**d** (Scheme 1). This same protocol led to catalysts with a methyl instead of a trifluoromethyl group (thioureas **7a**–**d** and **8a**–**d**).^{17,18}

The Michael addition of 1,3-dicarbonyl compounds to β -nitrostyrene has become an archetypical reaction to assess the performance of bifunctional catalysts.¹⁹ We employed 2,4-pentanedione as the source of the nucleophile for this reaction. In particular, we focused on the performance of the fluorinated

and nonfluorinated systems to compare thioureas with different HB donor properties.

We found that systems with an α -trifluoromethyl group have a strong match—mismatch relationship (Table 1, entries 1–8) as opposed to their nonfluorinated analogs (Table 1, entries 9–16). Additionally, we further studied the effect of the trifluoromethyl group on the yield and enantioselectivity by comparison of the diastereometic catalysts **5b** and **6b** along with **7b** and **8b**.²⁰

Similar trends concerning match—mismatch relationships were found with different nitroalkenes, as reported in Table 2: i.e., fluorinated catalysts **5b** and **6b** have a strong match mismatch relationship, in contrast with catalysts **7b** and **8b**. Interestingly, **6b** gives yields comparable with those of Takemoto but its performance is less susceptible to structural differences in the Michael acceptor. Because catalysts **6b** and **8b** only differ by three fluorine atoms, we expected that both systems with the

S,S configuration in the diamine to be the match combination. This, however, was not the case; catalyst 7b with the diamine having the *R*,*R* configuration gave better results in this regard.

We found similar yields, selectivities, and match-mismatch relationships for other pronucleophiles addressed in this work: i.e., those leading to products 17-20 (Table 3). We noted that the enantioselectivity of **6b** was comparable to that obtained from 7**b** with malonate nucleophiles.

Finally, we studied the performance of catalysts **6b** and **7b** in different solvents. We observed with catalyst **6b** much lower yields in ether solvents, but in all cases the reaction was stereo-selective (around 90% of the major enantiomer). On the other hand, the nonfluorinated catalyst **7b** presented the opposite trend; the yield was little affected and the stereoselectivity highly depended on the solvent used (Table 4).

The different behavior shown by the presented catalysts could also be attributed to the steric difference between the

methyl and trifluoromethyl groups. The van der Waals radii of $-CH_3$ and $-CF_3$ are 2.0 and 2.7 Å, respectively.²¹ In addition, the *A* value of trifluoromethyl is higher than that of isopropyl²² and hence it has been proposed that the $-CF_3$ group is of similar size to^{23a} or somewhat smaller than^{23b} $-CH(CH_3)_2$. We studied diastereomeric catalysts **21** and **22** with isopropyl substituents to find out if the steric demand is the factor responsible for the difference in the obtained results. We found that the catalysts featuring isopropyl groups have similar selectivity, but their corresponding enantiomeric excesses (60 and 56% as shown in Scheme 2) are considerably lower than those obtained with

Scheme 2. Yields and ee Values of the Michael Addition with Diastereomeric Catalysts 20 and 21

systems 6a and 7a (89 and 87%, respectively). We conclude that there should be other explanations for the observed enantioselectivity. The search for a suitable interpretation of the results considered up to this point motivated the theoretical studies presented below.

Computational Analysis. We now consider the reaction mechanism of the Michael addition. Takemoto proposed the first mechanism for this reaction, which involves the sequential activation of the electrophile and the nucleophile.^{2a} Afterward, Pápai²⁴ suggested a different mechanism with a lower activation energy than that of Takemoto. Our results with catalyst **6a**, shown in Figure S2 of the Supporting Information, are also consistent with Pápai's mechanism. In this reaction pathway (Figure 2), the nucleophile is first deprotonated by the tertiary amine **A**, and then migrates to the cavity of the thiourea **B**. Subsequently, the electrophile is attacked by the nucleophile–thiourea adduct, forming the trimolecular complex **C**, which is responsible for the orientation of the new carbon–carbon bond **TS**_P and the stereochemistry of the product **D**.

A model catalyst with a phenyl rather than a naphthyl group was used to reduce the number of atoms in the system and hence the computation time of the calculations. This is particularly reasonable inasmuch as the results obtained with catalysts including either $-C_6H_5$ or $-C_{10}H_7$ within their structure are similar (Table 1). In this way, we explored the energy profile with diastereometic catalysts 5a and 6a along with their nonfluorinated counterparts 7a and 8a.

The energy profiles in Figure 3 show that the activation barrier for the trifluoromethyl systems **6a** is less than the corresponding value for **5a** (4.6 and 6.7 kcal/mol, respectively) in accordance with the observed rate ($k_{obs} = 0.0092$ and 0.0066, respectively; see Figure S1 and Table S1 in the Supporting Information). In the nonfluorinated catalyst, the opposite configuration of the diamine has a smaller activation barrier (4.7 kcal/mol for **7a** and

Figure 2. Bifunctional catalyst mechanism proposed by Pápai.

Figure 3. Gibbs energy profile of the rate-limiting step in Pápai's mechanism for the Michael addition of 2,4-pentanedione and β -nitrostyrene with trifluoromethyl catalysts **5a** and **6a** and their nonfluorinated analogues **7a** and **8a**. The calculations were performed with the COSMO-(toluene)-RIJCOSX-MP2/aug-cc-pVDZ//M06-2x/6-31+g(d) level of theory. The structures of **C**, **TS**_P, and **D** are shown in Figure 2. (a) Catalysts with the *R*,*R* configuration in the diamine **5a** and **7a** generate the (*R*)-**9** product (b) Catalysts with the *S*,*S* configuration **6a** and **8a** yield the (*S*)-**9** compound.

5.2 kcal/mol for **8a**) also in agreement with the observed rates $(k_{obs} = 0.0331 \text{ and } 0.0042$, respectively). Although the theoretical calculations predict correctly the relative reaction rate for the diastereomeric pairs **5a** vs **6a** and **7a** vs **8a**, the computations are not fully consistent when the relative rates of all four systems are compared. This discrepancy may be attributable to factors such as product inhibition and the reversibility of the reaction,^{25,26} which are not taken into account in the computational analysis.

Figure 3 also shows that the fluorinated catalysts lead to different activation energies for the formation of each enantiomer, thereby favoring the observed enantioselectivity of the reaction. The calculated differences in activation energies are 2.0 and 3.5 kcal/mol for **5a** and **6a**, respectively, predicting correctly that **6a** is more enantioselective. With the nonfluorinated systems, these differences are 2.3 and 2.4 kcal/mol for **7a** and **8a**, respectively, which explains the lack of a strong match–mismatch relationship in these catalysts (Tables 1–3).

Further structural analysis of the transition states revealed the following.

(1) Thioureas attached with a trifluoromethyl group generate a shorter HB with the nucleophile,²⁶ as expected (Table S2 in the Supporting Information). These shorter and stronger hydrogen bonds in the fluorinated systems can be responsible for the lack of significant solvent effects on the enantioselectivity obtained with catalyst **6b**. This is buttressed by the fact that solvent effects are more pronounced in the ee achieved using 7b, as reported in Table 4.

(2) There are other interactions that involve the arylethyl groups which are particular to each catalyst. The structures of the systems with an *R*,*R* configuration of the diamine (**5a** and **7a**) present the phenyl ring on the same side of the approaching β -nitrostyrene in a way that a T-shaped $\pi - \pi$ contact is formed between the phenylethyl group of the thiourea and the $-C_6H_5$ part of PhCH=CHNO₂ (Figure 4). The observed distances between the centroids of the phenyl rings are 4.72 and 4.62 Å for **5a** and **7a**, respectively. These values are close to the optimal distance for this interaction (5.0 Å) computed with high-level ab initio calculations.²⁷

On the other hand, fluorinated and nonfluorinated catalysts with the $S_s S$ configuration in the diamine (8a and 6a) lead to

transition states with the $-CH_3$ and $-CF_3$ groups on the same side as the approaching nitrostyrene. Therefore, the phenylethyl group in catalyst **8a** is rotated to form the aforementioned $\pi - \pi$ interaction, whereas the structure produced with catalyst **6a** presents interactions between two fluorine atoms and an ortho C–H of the nitrostyrene molecule,²⁸ as shown in Figure 5 and confirmed with the topological analysis of the electron density (vide infra).

After having considered the energetic and structural aspects of the transition states of the Michael addition, we analyzed the interactions between the catalysts, the enolate, and the nitrostyrene by means of quantum chemical topology.²⁵ Figure 4 shows the molecular graph of the transition states for Pápai's mechanism formed with catalysts 5a and 7a. Both systems present bond paths between sulfur and the hydrogen atoms of the stereogenic carbon bonded to the thiourea. These trajectories of $\nabla \rho(\mathbf{r})$ suggest a moderate rigidity of the bifunctional catalysts, which facilitates the formation of the supramolecular complex. The interactions between both the fluorinated and nonfluorinated thioureas with the two reactants include five hydrogen bonds. Tables S3 and S5 in the Supporting Information report some selected topological properties of the charge distribution at the corresponding bond critical points. As expected, these hydrogen bonds are described as closed shell interactions, reflected in the sign of the Laplacian of the charge density, $\nabla^2 \rho(\mathbf{r}) > 0$, in the intermolecular region. The $-CF_3$ catalyst 5a has stronger NH···O hydrogen bonds ($E_{\rm H}$ in Table S3) and two CH··· π interactions, while the nonfluorinated compound 7a presents three CH \cdots π interactions. We also noted that the phenyl group in the catalyst responsible for these CH \cdots π interactions has a less negative charge in compound 5a due to the inductive effect of the trifluoromethyl group (Table S5). These weak interactions might explain the better performance of 7a in comparison with that of 5a. Considering the size of the aromatic ring in the catalyst, we can assume that the 9-anthracenyl group is too bulky for an optimal performance of the catalyst and the phenyl does not have a large enough molecular area for effective $\pi - \pi$ interactions. The naphthyl group provides a better compromise between the establishment of efficient $\pi \cdots \pi$ interactions and the avoidance of steric hindrance.

Article

Figure 4. Noncovalent interactions within the transition states for the Pápai's mechanism with catalysts 5a and 7a. The complete molecular graphs of these systems can be observed in Tables S4 and S6 of the Supporting Information.

Figure 5. Noncovalent interactions within the transition states for Pápai's mechanism with catalysts 6a and 8a. The complete molecular graphs of these systems can be found in Tables S5 and S7 in the Supporting Information.

Figure 5 shows a similar topological analysis of the electron density for the transition states with systems **6a** and **8a**. Once more, the fluorinated catalyst has stronger NH···O hydrogen bonds than the nonfluorinated analogue. In particular, compound **6a** forms the strongest NH_1 ···O₄ interaction (see Table S4 in the Supporting Information). Apart from these interactions, there are other hydrogen bonds between catalyst **6a** or **8a** and the reactants that depend on the conformation of the

-CHPhCX₃ group (X = F, H). The fluorinated catalyst presents HBs between two F atoms and an ortho hydrogen of the phenyl group of nitrostyrene, whereas the nonfluorinated system exhibits $-CH\cdots\pi$ bonds linking the two $-C_6H_5$ rings in the corresponding transition state. Again, the interactions between the reactants and catalyst **6a** are stronger than those found for **8a**. Overall, the topological analysis of the charge distribution indicates that the $-CF_3$ group leads to a stronger association of a

The Journal of Organic Chemistry

bifunctional thiourea with the reactants and thereby promotes the catalytic process more efficiently, in good agreement with the larger yield and enantiomeric excess of **6a** in comparison with **8a**. In addition, these CF···HC interactions could explain the ineffectiveness of systems with isopropyl (**21** and **22**). The *i*-Pr group produces no significant attractive forces and only provides steric hindrance. In the mismatch combination **21**, the isopropyl is on the same side of the approaching nitrostyrene, interfering in this way with the docking of this electrophile.

The computational analysis indicates that the fluorinated and nonfluorinated catalysts behave differently on account of their distinct secondary noncovalent interactions. The trifluoromethyl group in the catalyst **6a** is on the same side of the approaching β -nitrostyrene, and hence, the fluorine atoms form CF···H-C interactions. However, the nonfluorinated catalyst **7a** has the aromatic fragment on the same side of the approaching electrophile, which allows π - π interactions to be maximized. Therefore, although fluorinated catalyst **6a** presents the strongest NH···O HBs, nonfluorinated system **7a** exhibits a greater number of secondary noncovalent interactions (CH··· π and CH···O), which results in the similar performances of both catalysts.

CONCLUSION

We found that the incorporation of chiral groups with an α -trifluoromethyl moiety in bifunctional thioureas has a modest positive effect on the yield and selectivity of the Michael additions considered in this work. Nevertheless, the new catalysts **6** present stronger NH···O hydrogen bonds and CF···HC interactions with the reactants in comparison to their methylated counterparts. The methylated systems 7, on the other hand, exhibit more CH··· π and CH···O secondary interactions, which explains the comparable yield and selectivity. However, the chiral group presented in this work shows a good compromise between enhanced HB donor properties and controlled steric demands, which could be of interest to hydrogen-bonding organocatalysis.

EXPERIMENTAL SECTION

Computational Studies. The geometries of all intermediates and transition states were completely optimized with the M06-2x/6-31+G(d)³⁰ approximation as implemented in the Gaussian 09 package.³¹ Each stationary structure was characterized as a local minimum or a saddle point of first order by means of the computation of the corresponding harmonic frequencies. Intrinsic reaction coordinate calculations were carried out in all cases to verify that the localized transition state structures connect the two minima on the potential energy hypersurface associated with reactants and products. Solvent (toluene) effects were considered through the COSMO model and single-point energy calculations of all the stationary points with COSMO-(Toluene)-RIJCOSX-MP2/aug-cc-pVDZ.³²

The topological analysis of the electron density was done in accordance with the quantum theory of atoms in molecules (QTAIM)²⁹ and using the AIMAII program.³³ In particular, we considered the critical points of the charge distribution related to different elements of molecular structure defined in QTAIM, especially those associated with bonding between two atoms. The characterization of the different interactions between the bifunctional catalysts addressed in this study and the reactants of the Michael addition was done in terms of the properties of $\rho(\mathbf{r})$, including $\nabla^2 \rho(\mathbf{r})$ and the density of the potential energy, $V(\mathbf{r})$, from which hydrogen bond formation energies can be estimated as in ref 34.

General Considerations. All starting materials were used directly as obtained commercially. THF was distilled from sodium benzophenone ketyl. Flash column chromatography was carried out with silica gel 60 (0.4/0.63 mm, 230–400 mesh); TLC was performed with silica gel F254 plates. Melting points are uncorrected. ¹H and ¹³C NMR spectra

were recorded at 300 and 75 MHz, respectively. Chemical shifts (δ) are reported in ppm downfield from TMS, and coupling constants are in hertz. Mass spectra were obtained by EI. HRMS (FAB and DART) were measured with quadrupole and TOF mass spectrometers; CSP-HPLC analysis was performed using the indicated chiral column and UV detector.

2,2,2-Trifluoro-1-arylamines and precursors have been reported previously (see ref 15).

General Procedure for the Synthesis of Sulfinylimines 1a–d. One equivalent (15 mmol) of the corresponding aldehyde was dissolved in 40 mL of anhydrous THF under a nitrogen atmosphere. Then, we added 6.2 mL (30 mmol, 2 equiv) of titanium tetraethoxide and 1.8 g (15 mmol, 1 equiv) of (*S*)-*tert*-butylsulfinamide and stirred the mixture at room temperature for 17 h. The reaction mixture was poured into 40 mL of brine with vigorous stirring, and the resulting suspension was filtered over Celite. The cake was washed with EtOAc (20 mL × 3). The organic layer was separated, and the aqueous phase was extracted with EtOAc (15 mL × 3). The combined organic phases were dried with Na₂SO₄ and concentrated afterward. The final product was purified by FC with hexane/EtOAc 10/0 to 8/2. The acquired NMR spectra of target compounds matched those previously reported.

(\hat{S})-N-Benzylidene-tert-butanesulfinamide (1a).^{35a} Colorless liquid, 91% yield (2.86 g). $R_{\rm f} = 0.23$ (hexane/ethyl acetate, 9/1). [α]_D²⁵ = +97.5 (c 1.15, CHCl₃) (lit.^{35a} [α]_D²⁵ = +99.7 (c 1.15, CHCl₃)). ¹H NMR (300 MHz, CDCl₃): δ 8.44 (s, 1H), 7.68 (m, 2H), 7.42–7.19 (m, 3H), 1.10 (s, 9H). ¹³C NMR (75 MHz, CDCl₃): δ 162.4, 133.8, 132.1, 129.0, 128.6, 57.3, 22.3. General Procedure for Trifluoromethyl Addition (2a–d). A 20 mmol amount (1 equiv) of sulfinylimine 1 and 2.15 g (4 mmol, 0.2 equiv) of TBAT (tetrabutylammonium difluorotriphenylsilicate) were suspended in 60 mL of anhydrous THF under a nitrogen atmosphere. The reaction mixture was cooled to -50 °C, and then 3.6 mL (24 mmol, 1.2 equiv) of TMSCF₃ was added. The reaction mixture was stirred for 4 h at -50 °C and 20 h at -20 °C. The reaction was

The Journal of Organic Chemistry

quenched with 60 mL of aqueous ammonium chloride solution and extracted with EtOAc (50 mL \times 3). The combined organic phases were dried with Na₂SO₄ and then concentrated. The product was purified by FC with hexane/EtOAc as eluent (proportions indicated in each compound). The acquired NMR spectra of the compounds matched with previously reported data.^{15a}

(5)-*N*-[(*R*)-1-*P*^henyl-2,2,2-*trifluoroethyl*]-*tert-butanesulfinamide* (2a).^{15a} Purified by FC hexane/EtOAc, 7/3. White solid, 59% yield (3.30 g). $R_{\rm f} = 0.52$ (hexane/ethyl acetate, 1/1), Mp: 95–97 °C. [α]₂₅²⁵ = +75.2 (*c* 1, CHCl₃). ¹H NMR (300 MHz, CDCl₃): δ 7.42 (m, 5H), 5.00–4.70 (m, 1H), 3.68 (br, 1H), 1.25 (s, 9H). ¹³C NMR (75 MHz, CDCl₃): δ 133.8, 129.7, 129.3, 128.1, 124.7 (q, *J* = 281.6 Hz), 61.5 (q, *J* = 30.6 Hz), 57.1, 22.5. General Procedure for Amine Synthesis (3a–d). Sulfinamide 2 (15 mmol) was suspended in 10 mL of methanol. Then, 7.5 mL (30 mmol, 2 equiv) of 4 M HCl in dioxane was added. After 2 min the suspension became a clear solution and was stirred at room temperature for 1 h. It was concentrated and the residue dissolved in 60 mL of dichloromethane. The organic layer was washed with 60 mL of NaOH (10% aqueous), and the aqueous phase was re-extracted with DCM (40 mL × 2). The combined organic layers were dried with Na₂SO₄ (anhydrous) and concentrated. The recorded NMR spectra are similar to those of the amine hydrochlorides.^{15a}

(*R*)-1-Phenyl-2,2,2-trifluoroethylamine (**3***a*). Purified by FC hexane/EtOAc, 6/4. Colorless liquid, 97% yield (2.55 g). $R_f = 0.56$ (hexane/ethyl acetate, 6/4). $[\alpha]_D^{25} - 12.2$ (*c* 1, CHCl₃) (lit. ^{35f} $[\alpha]_D^{25} - 17.4$ (*c* 3.4, EtOH)). ¹H NMR (300 MHz, CDCl₃): δ 7.51–7.22 (m, 5H), 4.37 (q, J = 7.5 Hz, 1H), 1.80 (br, 2H). ¹³C NMR (75 MHz, CDCl₃): δ 135.6,

129.0, 128.7, 127.9, 125.8 (q, J = 281.2 Hz), 58.0 (q, J = 29.6 Hz). General Procedure for the Isothiocyanate Synthesis (4a–d). Amine 3 (5 mmol, 1 equiv) was dissolved in 20 mL of DCM and cooled to 0 °C. We added 0.42 mL of thiophosgene (5.5 mmol, 1.1 equiv) followed by 0.83 mL of triethylamine (6 mmol, 1.2 equiv). The reaction mixture was stirred for 30 min at 0 °C and 17 h at room temperature. The reaction mixture was washed with 10 mL of NaHCO₃ (saturated aqueous) and then was dried and concentrated. The product was purified by flash chromatography with a 95/5 hexane/EtOAc mixture, giving the different isothiocyanates as slightly yellow liquids. Note that (1) a better yield of 3a was obtained when the order of addition was reversed (DCM, thiophosgene, amine, and triethylamine) and (2) the isothiocyanate 4d has a low boiling point and, therefore, a one-pot procedure was performed to obtain catalysts 5d and 6d.

(*R*)-1-Phenyl-2,2,2-trifluoroethylisothiocyanate (4a). Purified by FC hexane/EtOAc, 95/5. Yellow liquid, 88% yield (956 mg). $R_{\rm f}$ = 0.60 (hexane/ethyl acetate, 9/1). $[\alpha]_{25}^{\rm 25}$ -7.2 (*c* 2.11, CHCl₃). ¹H NMR (300 MHz, CDCl₃): δ 7.46 (s, 5H), 5.19 (q, J = 6.5 Hz, 1H). ¹³C NMR (75 MHz, CDCl₃): δ 141.2, 130.5, 130.3, 129.2, 127.9, 122.7 (q, J = 282.5 Hz), 62.4 (q, J = 33.4 Hz). IR (film): $\tilde{\nu}$ (cm⁻¹) 3070, 3039, 2925, 2044, 1496, 1456, 1339, 1259, 1188, 1136, 871, 832, 757, 698, 632. MS-DART (positive): m/z (%) 218 (5) [M + H]⁺, 150 (100). HRMS (DART/TOF): m/z [M + H]⁺ calcd for C₉H₇F₃NS 218.0251; found 218.0246.

(*R*)-1-(1-Naphthyl)-2,2,2-trifluoroethylisothiocyanate (**4b**). Purified by FC hexane/EtOAc, 95/5. Slightly yellow solid, 87% yield (1.16 g). $R_{\rm f}$ = 0.56 (hexane/ethyl acetate, 9/1). Mp: 50–52 °C. $[\alpha]_{\rm D}^{25}$ +15.4 (c 1.43, CHCl₃). ¹H NMR (300 MHz, CDCl₃): δ 7.96–7.85 (m, 3H), 7.78 (d, *J* = 7.2 Hz, 1H), 7.69–7.44 (m, 3H), 6.07 (q, *J* =

6.1 Hz, 1H). ¹³C NMR (75 MHz, CDCl₃): δ 141.1, 133.9, 131.0, 130.6, 129.3, 127.5, 127.0, 126.4, 126.3, 125.3, 123.2 (q, *J* = 283.4 Hz), 122.1, 58.5 (q, *J* = 33.8 Hz). General Procedure for the Preparation of Bifuncional Catalysts 5–8 and T. The corresponding isothiocyanate (2 mmol, 1 equiv) was dissolved in 7 mL of DCM. *N*,*N*-Dimethyl-2-aminocyclohexanamine (2.4 mmol, 1.2 equiv) was added, and the mixture was stirred overnight at room temperature. The reaction mixture was concentrated and the catalyst purified by flash chromatography with EtOAc as eluent followed by a 90/10/1 CH₂Cl₂/CH₃OH/NH₄OH mixture.

For catalysts 5d-8d the isothiocyanate needed for the thiourea has a low boiling point. We applied a one-pot protocol to circumvent this issue. After the reaction with thiophosgene occurred, it was washed with a solution of aqueous sodium bicarbonate and dried with anhydrous Na₂SO₄ prior to the addition of the diamine. Thus, the yield was calculated from the starting amine 3d or the nonfluorinated analogue.

1-[3,5-Bis(trifluoromethyl)phenyl]-3-[(1R,2R)-2-(dimethylamino)cyclohexyl]thiourea (T).^{2a} White solid, 82% yield (678 mg). $R_{\rm f} = 0.38$ $(CH_2Cl_2/CH_3OH/NH_4OH, 90/10/1)$. General Procedure for Michael Addition to Nitrostyrenes. We dissolved 29.8 mg (1 equiv, 0.2 mmol) of β -nitrostyrene and 0.05 equiv (0.01 mmol) of the bifunctional thiourea in 0.66 mL of dry toluene in a 4 mL screw cap dram vial with a magnetic stirrer. The reaction mixture was stirred for 10 min, and then the nucleophile was added (1.5 equiv. 0.30 mmol). The mixture was agitated for 24 h at 20 °C. The solvent was removed and purified in FC with a 7/3 hexane/EtOAc mixture. The reported yields and weights were obtained with catalyst **6b**.

HPLC: Chiralpak IC3, hexane/ethanol 85/15, 0.6 mL/min, λ 220 nm, retention times 15.6 min (S), 20.1 (R).

(S)-3-(1-(4-Methoxyphenyl)-2-nitroethyl)pentane-2,4-dione (11).^{36a} White solid, 90% yield (50.2 mg). Mp: 100–103 °C. $[\alpha]_D^{25}$ +153.4 (*c* 1.0, CHCl₃) (89% ee) (lit.^{36a} R enantiomer $[\alpha]_D^{25}$ –191.6 (*c* 1, CHCl₃), 98% ee). ¹H NMR (300 MHz, CDCl₃): δ 7.10 (d, *J* = 8.7 Hz, 2H), 6.84 (d, *J* = 8.8 Hz, 2H), 4.60 (d, *J* = 1.4 Hz, 1H), 4.58 (s, 1H), 4.33 (d, *J* = 10.9 Hz, 1H), 4.25–4.14 (m, 1H), 3.77 (s, 3H), 2.28 (s, 3H), 1.94 (s, 3H). ¹³C NMR (75 MHz, CDCl₃): δ 201.8, 201.1, 159.6, 129.1, 127.66, 114.7, 78.4, 71.0, 55.2, 42.1, 30.3, 29.4. HPLC: Chiralpak IC3, hexane/ethanol 85/15, 0.6 mL/min, λ 254 nm, retention times 12.0 min (*S*), 16.5 min (*R*).

(S)-3-(1-(4-Chlorophenyl)-2-nitroethyl)pentane-2,4-dione (**12**).^{36b} White solid, 94% yield (53.3 mg). Mp: 112–115 °C, $[\alpha]_{25}^{25}$ +131.7 (*c* 1.0, CHCl₃) (84% ee) (lit.^{36b} (R) enantiomer mp 119–121 °C $[\alpha]_{25}^{25}$ –132.5 (*c* 1.04, CHCl₃), 88% ee). ¹H NMR (300 MHz, CDCl₃): δ 7.35 (d, J = 8.6 Hz, 2H), 7.17 (d, J = 8.4 Hz, 2H), 4.74–4.57 (m, 2H), 4.36 (d, J = 10.7 Hz, 1H), 4.32–4.17 (m, 1H), 2.33 (s, 3H), 2.01 (s, 3H). ¹³C NMR (75 MHz, CDCl₃): δ 201.5, 200.7, 134.8 (2C), 129.7, 129.5, 78.1, 70.8, 42.3, 30.6, 29.8. HPLC: Chiralpak IC3, hexane/ethanol 85/15, 0.6 mL/min, λ 220 nm, retention times 7.0 min (*S*), 9.8 min (*R*). (S)-3-(2-Nitro-1-(4-nitrophenyl)ethyl)pentane-2,4-dione (13).^{36c} Beige solid, 86% yield (50.6 mg). Mp: 110–113 °C. $[a]_D^{25}$ +99.9 (c 1.03, CHCl₃) (84% ee). ¹H NMR (300 MHz, CDCl₃): δ 8.21 (d, J = 8.8 Hz, 2H), 7.41 (d, J = 8.8 Hz, 2H), 4.77–4.55 (m, 2H), 4.38 (s, 2H), 2.33 (s, 3H), 2.03 (s, 3H). ¹³C NMR (75 MHz, CDCl₃): δ 200.9, 143.8, 129.3, 124.6, 77.5, 70.3, 42.5, 30.7, 30.1. HPLC: Chiralpak IC3, hexane/ ethanol 85/15, 0.6 mL/min, λ 250 nm, retention times 11.6 min (*S*), 16.1 (*R*).

(S)-3-(1-(2-Bromophenyl)-2-nitroethyl)pentane-2,4-dione (14).^{36a} White solid, 92% yield (60.3 mg). Mp: 77–79 °C, $[\alpha]_{D}^{25}$ +185.0 (*c* 1, CHCl₃) (84% ee) (lit.^{36a} R enantiomer $[\alpha]_{D}^{25}$ -218.5 (*c* 1, CHCl₃), 98% ee). ¹H NMR (300 MHz, CDCl₃): δ 7.63 (m, 1H), 7.30 (m, 1H), 7.22–7.09 (m, 2H), 4.93–4.80 (m, 1H), 4.80–4.52 (m, 3H), 2.29 (s, 3H), 2.05 (s, 3H). ¹³C NMR (75 MHz, CDCl₃): δ 202.1, 201.0, 135.3, 134.2, 130.1, 129.1, 128.4, 124.7, 76.4, 69.3, 41.3, 31.1, 28.5. HPLC: Chiralpak IA, hexane/ethanol 85/15, 0.8 mL/min, λ 220 nm, retention times 11.1 min (S), 13.8 (R).

(5)-3-(1-(Naphthalen-1-yl)-2-nitroethyl)pentane-2,4-dione (15).^{36b} Yellow liquid, 82% yield (49.1 mg). $[\alpha]_D^{25}$ +171.4 (*c* 1.50, CHCl₃) (87% ee) (lit.^{36b} *R* enantiomer $[\alpha]_D^{25}$ -182.0 (*c* 1.0, CHCl₃), 95% ee). ¹H NMR (300 MHz, CDCl₃): δ 8.18 (d, *J* = 8.3 Hz, 1H), 7.85 (dd, *J* = 24.8, 8.0 Hz, 2H), 7.74–7.48 (m, 2H), 7.48–7.12 (m, 2H), 5.46–5.11 (m, 1H), 5.07–4.48 (m, 3H), 2.32 (s, 3H), 1.87 (s, 3H). ¹³C NMR (75 MHz, CDCl₃): δ 202.4, 200.9, 134.4, 132.1, 130.9, 129.6, 129.3, 127.5, 126.5, 125.4, 124.99 (br), 122.0, 77.9, 70.6, 36.6, 31.1, 28.8. HPLC: Chiralpak IA, hexane/ethanol 85/15, 0.8 mL/min, λ 220 nm, retention times 11.7 min (*S*), 14.5 min (*R*).

(*R*)-3-(2-*Nitro*-1-(*thiophen*-2-*yl*)*ethyl*)*pentane*-2,4-*dione* (**16**).^{17c} Beige solid, 69% yield (35.2 mg). $[\alpha]_{D}^{25}$ +126.5 (*c* 1.10, CHCl₃) (89% ee). ¹H NMR (300 MHz, CDCl₃): δ 7.31–7.19 (m, 1H), 7.01–6.83 (m, 2H), 4.66 (d, *J* = 5.3 Hz, 2H), 4.61–4.49 (m, 1H), 4.41 (d, *J* = 10.1 Hz, 1H), 2.30 (s, 3H), 2.08 (s, 3H). ¹³C NMR (75 MHz, CDCl₃): δ 201.6, 200.8, 138.6, 127.5, 127.1, 125.9, 78.6, 71.2, 38.3, 30.7, 29.8. HPLC: Chiralcel OJ, hexane/ethanol 70/30, 1.0 mL/min, λ 220 nm, retention times 33.4 min (*S*), 41.9 min (*R*).

Dimethyl (5)-2-(1-Phenyl-2-nitroethyl)malonate (17).^{2b} White solid, 69% yield (38.8 mg). Mp: 50–55 °C. $[\alpha]_D^{25}$ +6.0 (*c* 1.10, CHCl₃) (87% ee) (lit.^{2b} R enantiomer mp 63–64 °C, $[\alpha]_D^{2b}$ –6.15 (*c* 1.10, CHCl₃), 89% ee). ¹H NMR (300 MHz, CDCl₃): δ 7.45–7.13 (m, 5H), 5.03–4.77 (m, 2H), 4.25 (td, *J* = 8.8, 5.6 Hz, 1H), 3.87 (d, *J* = 9.1 Hz, 1H), 3.76 (s, 3H), 3.56 (s, 3H). ¹³C NMR (75 MHz, CDCl₃): δ 168.0, 167.4, 136.2, 129.2, 128.6, 128.0, 54.9, 53.2, 53.0, 43.1. HPLC: Chiralpak IC3, hexane/ethanol 85/15, 0.6 mL/min, λ 220 nm, retention times: 9.1 min (*R*), 10.6 (*S*).

Dimethyl (R)-2-Methyl-2-(1-phenyl-2-nitroethyl)malonate (18).^{2b} White solid, 57% yield (33.6 mg). Mp: 124–127 °C. $[\alpha]_{25}^{25}$ –28.5 (*c* 1.00, CHCl₃) (93% ee) (lit.^{2b} S enantiomer mp 130–132 °C, $[\alpha]_{25}^{25}$ +32.3 (*c* 1.06, CHCl₃), 93% ee). ¹H NMR (300 MHz, CDCl₃): δ 7.37–7.27 (m, 3H), 7.19–7.12 (m, 2H), 5.11–4.99 (m, 2H), 4.21–4.14 (m, 1H), 3.78 (s, 3H), 3.74 (s, 3H), 1.35 (s, 3H). ¹³C NMR (75 MHz, CDCl₃): δ 171.5, 170.9, 135.1, 129.1, 129.0, 128.7, 56.9, 53.2, 53.0, 48.5, 20.5. HPLC: Chiralpak IC3, hexane/ethanol 85/15, 0.6 mL/min, λ 220 nm, retention times 7.1 min (*R*), 9.2 (*S*).

Ethyl ξ-1-((R)-2-Nitro-1-phenylethyl)-2-oxocyclopentane-1-carboxylate (19). ^{36d} Colorless liquid, 96% yield (58.6 mg). ¹H NMR (300 MHz, CDCl₃): δ 7.46–7.12 (m, 5H), 5.18 (dd, J = 13.6, 3.9 Hz, 1H), 5.02 (dd, J = 13.5, 10.9 Hz, 1H), 4.21 (q, J = 7.1 Hz, 2H), 4.08 (dd, J = 10.9, 3.9 Hz, 1H), 2.58–2.22 (m, 3H), 2.05–1.79 (m, 3H), 1.27 (t, J = 7.1 Hz, 3H). ¹³C NMR (75 MHz, CDCl₃): δ 212.5, 169.4, 135.4, 129.4, 128.9, 128.4, 76.6, 62.5, 62.3, 46.3, 38.0, 31.3, 19.5, 14.1. HPLC: Chiralpak IC3, hexane/ethanol 85/15, 0.6 mL/min, λ 220 nm, retention times 9.1 min (R), 11.3 (S).

(*R*)-2-Hydroxy-3-(2-nitro-1-phenylethyl)naphthoquinone (**20**).^{36e} Yellow solid, 84% yield (54.3 mg). Mp: 148–150 °C. $[\alpha]_{25}^{25}$ –15.6 (*c* 0.33, CHCl₃) (96% ee) (lit.^{31e} S enantiomer mp 147–149 °C, $[\alpha]_{25}^{25}$ +37 (*c* 1.0, acetone)). ¹H NMR (300 MHz, CDCl₃): δ 8.20–7.99 (m, 2H), 7.89–7.62 (m, 3H), 7.55–7.41 (m, 2H), 7.38–7.19 (m, 3H), 5.56–5.41 (m, 1H), 5.38–5.25 (m, 1H), 5.22–5.08 (m, 1H). ¹³C NMR (75 MHz, CDCl₃): δ 183.6, 181.1, 153.2, 137.5, 135.4, 133.2, 132.6, 129.0, 128.3, 127.8, 127.2, 126.3, 120.8, 76.4, 39.7.

The Journal of Organic Chemistry

HPLC: Chiralcel OJ, hexane/ethanol 70/30, 0.8 mL/min, λ 220 nm, retention times 22.2 min (*S*), 41.4 (*R*).

ACKNOWLEDGMENTS

We thank the DGAPA-UNAM (project IN209915) and CONACyT (grant 254014) for financial support, and the DGCTIC, UNAM, for supercomputer resources (SC16-1-IR-109 and SC16-1-IG-99). E.I.J., W.E.V.N., and J.V.-C. gratefully acknowledge the CONACyT/México for Ph.D. scholarships. We also thank L. C. Márquez, E. García, and L. M. Ríos for HPLC analysis and J. Pérez, L. Velasco, M. C. García for mass analysis. T R.-R. and M.H.-R. express their gratitude to M. A. Peña, M. I. Chávez, E. Huerta, B. Quiroz, I. M. Aguilar, G. Cortés, and D. Vázquez for technical support.

(10) Organocatalysts with one fluorine atom have been reported:
(a) Sparr, C.; Schweizer, W. B.; Senn, H. M.; Gilmour, R. Angew. Chem., Int. Ed. 2009, 48, 3065–3068. (b) Zimmer, L.; Sparr, C.; Gilmour, R. Angew. Chem., Int. Ed. 2011, 50, 11860–11871. (c) Molnár, G.; Tanzer, E.-M.; Daniluc, C.; Gilmour, R. Chem. - Eur. J. 2014, 20, 794–800. (d) Cahard, D.; Bizet, V. Chem. Soc. Rev. 2014, 43, 135–147.

(11) Trejo-Huizar, K. E.; Ortiz-Rico, R.; Peña-González, M. A.; Hernández-Rodríguez, M. New J. Chem. **2013**, *37*, 2610–2613.

(12) The acidity of the bifunctional thiourea correlates with the yield in the reaction and other HB catalysis: (a) Li, X.; Deng, H.; Zhang, B.; Li, J.; Zhang, L.; Luo, S.; Chen, J.-P. *Chem. - Eur. J.* **2010**, *16*, 450–455. (b) Walvoord, R. R.; Huynh, P. N. H.; Kozlowski, M. C. J. Am. Chem. Soc. **2014**, *136*, 16055–16065.

(13) Electron-withdrawing groups with good hydrogen bond acceptors could deactivate the catalyst by intramolecular hydrogen bonds. For example *N*-acyl ureas have a strong intramolecular hydrogen bond. (a) Lessene, G.; Smith, B. J.; Gable, R. W.; Baell, J. B. *J. Org. Chem.* **2009**, 74, 6511–6525. (b) Abraham, M. H.; Abraham, R. J.; Acree, W. E., Jr.; Aliev, A. E.; Leo, A. J.; Whaley, W. L. *J. Org. Chem.* **2014**, 79, 11075–11083.

(14) The enhanced acidity of fluorine-containing alcohols is already known: (a) Vuluga, D.; Legros, J.; Crousse, B.; Slawin, A. M. Z.; Laurence, C.; Nicolet, P.; Bonnet-Delpon, D. J. Org. Chem. 2011, 76, 1126–1133. Nevertheless, fluorine incorporation in molecules does not always increase their acidity. It has been reported that in conformationally restricted cyclohexanols an internal OH…F interaction diminishes the acidity of alcohol; see: Graton, J.; Wang, Z.; Brossard, A.-M.; Monteiro, D. G.; Le Questel, J.-Y.; Linclau, B. Angew. Chem., Int. Ed. 2012, 51, 6176–6180.

Q. Hugo García Hernández

Agradecimientos

Al Programa de Maestría y Doctorado en Ciencias Químicas y al Instituto de Química de la UNAM, por las facilidades otorgadas para el desarrollo de este trabajo.

Al Dr. Marcos Hernández Rodríguez, por el incontable tiempo y las infinitas enseñanzas que recibí bajo su asesoría.

A la Q. María de los Ángeles Peña González, por los espectros que me ayudo a obtener y la capacitación que recibí para el uso de los equipos de RMN. A la M. en C. Lucía del Carmen Márquez Alonso, a la Q. Eréndira García Ríos y a la M. en C. Lucero Mayra Rios Ruiz por los cromatográmas que me ayudaron a obtener. Al Dr. Francisco Javier Pérez Flores, al I.Q. Luis Velasco Ibarra y a la Dra. María del Carmen García González por los espectros de masas que me ayudaron a obtener.

A CONACyT México, por la beca otorgada con el número 625304 y número de becario 336324.

A DGAPA-UNAM (proyecto IN209915) y CONACyT (proyecto 254014) por los financiamientos otorgados. Se emplearon recursos de supercomputo a través de DGCTIC, UNAM (SC16-1-IR-109).

A los miembros de mi jurado: al Dr. José Luis Arias Téllez, la Dra. Teresa Mancilla Percino, al Dr. Héctor García Ortega, al Dr. Vojtech Jancik y a la Dra. María del Carmen Virginia Ortega Alfaro, por el tiempo que se tomaron para leer el presente informe y por los consejos que recibí de cada uno de ellos.

Este trabajo se desarrolló en el laboratorio 1-2 del Instituto de Química, UNAM.

Este trabajo se desarrolló en el laboratorio 1-2 del edificio A del Instituto de Química de la UNAM. Con financiamientos de DGAPA-UNAM (proyecto IN209915) y CONACyT (proyecto 254014). Se emplearon recursos de supercómputo a través de DGCTIC, UNAM (SC16-1-IR-109). También se agradece a CONACyT, México por la beca doctoral (Becario No. 240069).

AGRADECIMIENTOS

- A la máxima casa de estudios: Universidad Nacional Autónoma de México (UNAM) por brindarme el conocimiento y las herramientas necesarias en mi formación profesional.
- Al Programa de Apoyo a Proyectos de Investigación e Innovación Tecnológica (PAPIIT) por la financiación a través del proyecto IN209915.
- Al **Consejo Nacional de Ciencia y Tecnología (CONACyT)** por el subsidio 254014 y la beca otorgada durante mis estudios de doctorado (Becario No. 240069).
- A la Dirección General de Cómputo y de Tecnologías de Información y Comunicación (DGCTIC) por los recursos de computación (SC16-1-IR-109).
- A mi asesor, el Dr. Marcos Hernández Rodríguez que no sólo me indicó la importancia de la organocatálisis en la química sino también me *espoilió* varias series, incluida la muerte de un Stark en Game of Thrones, no lo olvidaré.
- Al Dr. Tomás Rocha Rinza por su característico asesoramiento y colaboración en la parte computacional y a Wilmer Esteban Vallejo por el desarrollo de los cálculos computacionales; además, un gran amigo (*a.k.a. vato loco*) a pesar de no dejar de quejarse de que toda la comida en México "pica" aunque no tenga chile.
- Al alumno Carlos Román por su apoyo y perseverancia en el desarrollo de la síntesis de las azlactonas.
- Al personal técnico del Instituto de Química. A la Q. María de los Ángeles Peña, la M. en C. Elizabeth Huerta, la Dra. María Isabel Chávez y al M. en C. Héctor Ríos por la resonancia magnética nuclear. La M. en C. Lucero Mayra Rios, la Q. Eréndira García y la M. en C. Lucía del Carmen Márquez por los análisis de HPLC. La Dra. María del Carmen García, el Dr. Francisco Javier Pérez y al I.Q. Luis Velasco por los análisis de espectrometría de masas. A la Q.F.B. María del Rocío Patiño por los análisis de infrarrojo y rotación óptica.
